**LOW-SMOKE SELF-EXTINGUISHING CABLE AND FLAME-RETARDANT
COMPOSITION USED THEREIN.**

The present invention relates to cables, in particular for low-voltage electrical energy distribution or for telecommunications, these cables having low-smoke self-extinguishing properties, and to the flame-retardant compositions used therein.

Self-extinguishing cables can be produced having a flame-retardant coating made from a polymer composition to which fire-resistant properties have been given by adding a suitable additive. Polyolefin-based compositions based, for example, on polyethylene or ethylene/vinyl acetate copolymers, containing an organic halide combined with antimony trioxide as flame-retardant additive can, for example, be used for this purpose. However, halogenated flame-retardant additives have many drawbacks since they partially decompose during processing of the polymer, giving rise to halogenated gases that are toxic to workers and corrode metal parts of the polymer-processing equipment. In addition, when they are placed directly in a flame, their combustion gives rise to large amounts of fumes containing toxic gases. Similar drawbacks are encountered when polyvinylchloride (PVC) supplemented with antimony trioxide is used as base polymer.

Therefore, in recent years the production of self-extinguishing cables has been directed toward halogen-free compositions, using as flame-retardant filler inorganic oxides, preferably in hydrate or hydroxide form, in particular magnesium hydroxide or aluminium hydroxide.

Aluminium hydroxide starts to decompose at a relatively low temperature (about 190°C), which can result in various drawbacks during extrusion of the

polymer composition, with formation of bubbles and defects in the final product. Therefore, the use of aluminium hydroxide as flame retardant is generally limited to polymer materials which do not require high processing temperatures. In contrast, magnesium hydroxide has a decomposition temperature of about 340°C and is characterized by greater heat stability and a high decomposition enthalpy. These properties make magnesium hydroxide particularly suitable as flame retardant filler in polymer compositions for coating cables, which require high extrusion temperatures and a small number of morphological defects.

However, the use of magnesium hydroxide as a flame-retardant filler does have certain drawbacks. Firstly, in order to obtain an efficient flame-retardant effect, very large amounts of magnesium hydroxide must be added to the polymer material, generally about 120-250 parts by weight relative to 100 parts by weight of polymer material. Such high levels of filler lead to a reduction in processability and in mechanical and elastic properties of the resulting mixture, in particular as regards impact resistance, elongation and stress at break.

In the US patent No. 4,145,404 these drawbacks are attributed to the low affinity of natural magnesium hydroxide, obtained for example by grinding minerals such as brucite, with the polymer material, in particular when the polymer is of low polarity, as in the case of polyolefins.

In the patent EP-780,425 it is pointed out that the presence of different metal impurities, such as iron or manganese salts, in magnesium hydroxide of natural origin causes degradation of the polymer matrix into which the magnesium hydroxide is inserted.

Therefore, research efforts have been directed towards modifying properties of magnesium hydroxide to

improve its compatibility with the polymer matrix and its degree of purity. Various synthetic methods have thus been developed in which magnesium hydroxide is produced by adding alkalis to an aqueous solution of a soluble
5 salt thereof and subsequent precipitation of the hydroxide by heating at high pressure (see for example patent US-4,098,762 or the above-mentioned patents EP-780,425 and US-4,145,404). In this way, a magnesium hydroxide is obtained with a high degree of purity and
10 high structural uniformity with formation of crystallites of flattened hexagonal shape with an average diameter not greater than 2 μm and a specific surface area, measured by BET method, not greater than 20 m^2/g .

However, the use of synthetic magnesium hydroxide as
15 flame-retardant filler has a considerable impact on the cost of the finished product, so as to make flame-retardant systems based on magnesium hydroxide non-competitive when compared with the halogen-containing flame-retardant compositions described above.

20 In certain cases attempts have been made to improve properties of natural magnesium hydroxide using suitable grinding and/or surface treatment processes.

For example, Japanese patent application JP-01-294792 (Kokai) describes a process for the production of
25 magnesium hydroxide, in which natural brucite is wet-ground so as to obtain an average particle diameter of between 2 and 6 μm , and then surface-treated with a fatty acid ammonium salt, and eventually dried. The resulting magnesium hydroxide would be resistant to efflorescence
30 phenomena caused by carbonation of magnesium hydroxide by atmospheric carbon dioxide. The process of wet-grinding is considered essential to make the particle size of the product more uniform without increasing its lattice distortion coefficient which is thought to be responsible
35 for high resistance to carbonation of natural magnesium

hydroxide. The surface treatment is thought to improve dispersibility of the filler in the polymer matrix. The magnesium hydroxide thus obtained is claimed to be useful as a flame-retardant for polyolefin resins. In particular, the examples describe compositions with flame-retardant properties based on ethylene/vinyl acetate (EVA) and ethylene/ethyl acrylate (EEA) copolymers.

Japanese patent application JP-03-231,944 (Kokai) describes polyolefin-based compositions having flame-retardant properties and containing magnesium hydroxide with an average particle diameter of between 3 and 13 μm and the following particle size distribution: 1-20% by weight of particles with a diameter less than or equal to 1 μm ; 55-98% by weight of particles with a diameter between 1 and 15 μm ; 1-25% by weight of particles with a diameter between 15 and 50 μm . This particle size distribution is believed to afford higher flame resistance, which would be accompanied by good mechanical strength, flexibility and processability. A magnesium hydroxide with these properties would be obtainable by suitable grinding of natural brucite, followed by sieving or addition of another material of predetermined particle size. According to the description given in the above-mentioned patent application, this type of magnesium hydroxide would be useful as a flame-retardant filler for polyolefins such as polyethylene, olefinic rubbers, polypropylene, polybutene and the like. Particular mention is made of ultra-low-density polyethylene (ULDPE) having a density of 0.860-0.910 g/cm^3 , obtainable by copolymerization of ethylene with an α -olefin in the presence of a conventional Ziegler-Natta catalyst based on titanium and/or vanadium compounds.

Lastly, Japanese patent application JP-05-17692 (Kokai) describes polymer compositions having flame-

retardant properties and containing natural magnesium hydroxide which has previously been ground and surface-treated with a fatty acid or a fatty acid salt, or alternatively with a silane or a titanate acting as coupling agent. These compositions would be characterized by high resistance to acid attacks. The subsequent Japanese patent application JP-07-161230 (Kokai) describes compositions similar to the above, pointing out that, in order to decrease the hygroscopicity of magnesium hydroxide, the latter must be surface-treated with the same products as mentioned above, in amounts of between 0.5 and 5% by weight relative to the magnesium hydroxide weight. In both of the above-mentioned Japanese patent applications, polyolefins such as polyethylene, ethylene/propylene rubbers, acrylic rubbers and the like are cited as polymeric materials, and flame-retardant compositions based on ethylene/ethylacrylate (EAA) polymers are given as particular examples. No information is provided regarding mechanical, elastic or processability properties of the resulting mixtures.

From the foregoing, it is clear that in the prior art considerable efforts have been made to improve the properties of flame-retardant polymer compositions containing magnesium hydroxide by modifying the properties of magnesium hydroxide itself, in terms of crystallinity, particle size distribution and/or surface properties. These modifications have been achieved either by developing synthetic processes starting from soluble magnesium salts or by appropriately modifying and treating natural magnesium hydroxide. For the purposes of the present invention, with enhanced flame-retardant properties it is meant that a cable passes a test as defined by standard CEI 332-1; with enhanced mechanical properties it is meant a high elongation at break value and a relatively low modulus, which are capable of

determining a cable flexibility which is suitable for use; in particular, it is meant that mechanical properties are essentially not lower than those of cables using compositions of known type, for example halogenated
5 compositions.

The Applicant has now found that it is possible to produce self-extinguishing, halogen-free cables producing a low level of fumes and having high flame resistance and excellent mechanical performances by using natural
10 magnesium hydroxide as flame-retardant filler and, as polymer matrix, a polymeric mixture comprising a crystalline propylene homopolymer or copolymer and a copolymer of ethylene with an alpha-olefin, and optionally with a diene, characterized by uniform
15 distribution of the alpha-olefin among the copolymer molecules.

Therefore, according to a first aspect, the present invention relates to a cable with self-extinguishing properties, comprising a conductor and a flame-retardant
20 coating, characterized in that the said flame-retardant coating comprises:

(a) a crystalline propylene homopolymer or copolymer;

(b) a copolymer of ethylene with at least one alpha-
25 olefin, and optionally with a diene, said copolymer (b) being characterized by a composition distribution index greater than 45%, said index being defined as the weight percentage of copolymer molecules having an alpha-olefin content within 50% of the average total molar content of
30 alpha-olefin;

(c) natural magnesium hydroxide in an amount such as to impart flame-retardant properties.

In a second aspect, the present invention relates to a flame-retardant composition comprising:

35 (a) a crystalline propylene homopolymer or

copolymer;

(b) a copolymer of ethylene with at least one alpha-olefin, and optionally with a diene, said copolymer (b) being characterized by a composition distribution index
5 greater than 45%, said index being defined as the weight percentage of copolymer molecules having an alpha-olefin content within 50% of the average total molar content of alpha-olefin;

(c) natural magnesium hydroxide in an amount such as
10 to impart flame-retardant properties.

The composition distribution index provides an indication of the distribution of the alpha-olefin among the copolymer molecules (the higher the value of this index, the more homogeneous the distribution of the
15 comonomer among the copolymer molecules), and can be determined by Temperature Rising Elution Fractionation, as described, for example, in patent US-5,008,204 or in Wild et al., J. Poly. Sci. Poly. Phys. Ed., Vol. 20, p. 441 (1982).

20 In the Applicant's view, the composition distribution index is related to the ability of the copolymers of ethylene with an alpha-olefin, and optionally with a diene, to incorporate and disperse large amounts of the flame-retardant filler, thereby
25 obtaining a mixture having excellent flame-resistance and, at the same time, good processability and improved mechanical properties. Given a certain ratio between flame-retardant filler and polymer matrix, it is important to determine the minimum value of this index
30 which is sufficient to obtain the desired combination of mechanical properties and processability.

Moreover, the presence in the polymer mixture of a crystalline propylene homopolymer or copolymer makes it possible to obtain a thermoplastic coating which has
35 increased thermocompression resistance even at the

maximum operating temperatures, so as to pass the thermocompression test described in CEI standard 20-34/3-1. This test consists in subjecting the coating of a cable specimen to a predetermined compression at a predetermined temperature and for a predetermined time. At the end of the test, the flattening degree of the coating, expressed as percentage of the residual thickness relative to the initial thickness of the coating, is measured: the sample passes the test if its residual thickness is greater than 50% of its initial thickness.

In a further aspect, the present invention relates to a method for obtaining a cable having improved mechanical properties and increased fire resistance, said method comprising the following steps: (1) preparing a polymer mixture having flame-retardant properties; (2) extruding said mixture on a conductor optionally pre-coated with an insulating layer, characterized in that step (1) comprises mixing a predetermined amount of natural magnesium hydroxide with a polymer mixture comprising:

(a) a crystalline propylene homopolymer or copolymer, as a polymeric component capable of increasing the thermocompression resistance of the flame-retardant coating; and:

(b) a copolymer of ethylene with at least one alpha-olefin, and optionally with a diene, capable of dispersing natural magnesium hydroxide, so as to improve processability of the mixture and enhance mechanical properties of the flame-retardant coating.

The amount of natural magnesium hydroxide to be added is predetermined so as to obtain a cable which is capable of passing the fire-resistance test according to CEI standard 332-1. The amount of propylene homopolymer or copolymer (a) is such that the flame-retardant coating

obtained after extrusion has a value of thermocompression resistance, measured at 100°C according to CEI standard 20-34/3-1, greater than 50%. The amount of copolymer (b) is such that the flame-retardant coating obtained after
5 extrusion has an elongation at break, measured according to CEI standard 20-34 § 5.1, of at least 100%, preferably of at least 150%, and a modulus at 20%, measured according to CEI standard 20-34 § 5.1, of less than 12 MPa, preferably less than 7 MPa.

10 Figure 1 shows, in a schematic form, the cross-section of a low-voltage electrical cable of unipolar type according to one embodiment of the present invention, this cable comprising a conductor (1), an inner layer (2) acting as electrical insulation and an
15 outer layer (3) acting as a protective sheath with flame-retardant properties, consisting of the composition according to the present invention.

The term "low voltage" is understood generally to refer to a voltage of less than 2 kV, preferably less
20 than 1 kV.

The inner layer (2) may consist of a halogen-free, crosslinked or non-crosslinked polymer composition with electrically insulating properties which is known in the art, selected, e.g., from: polyolefins (homopolymers or
25 copolymers of different olefins), olefin/ethylenically unsaturated ester copolymers, polyesters, polyethers, polyether/polyester copolymers, and mixtures thereof. Examples of such polymers are: polyethylene (PE), in particular linear low density PE (LLDPE); polypropylene
30 (PP); propylene/ethylene thermoplastic copolymers; ethylene/propylene rubbers (EPR) or ethylene/propylene/diene rubbers (EPDM); natural rubbers; butyl rubbers; ethylene/vinylacetate (EVA) copolymers; ethylene/methylacrylate (EMA) copolymers;
35 ethylene/ethylacrylate (EEA) copolymers;

ethylene/butylacrylate (EBA) copolymers; ethylene/ alpha-olefin copolymers, and the like. It is also possible to use the same polymer base for the inner layer (2) as well as for the outer layer (3), namely the mixture of (a) and
5 (b) as defined above.

Alternatively, a self-extinguishing cable according to the present invention may consist of a conductor coated directly with the flame-retardant composition described above, without interposing other insulating
10 layers. In this way, the flame-retardant coating also acts as electrical insulator. A thin polymer layer acting as an anti-abrasive can then be externally added, optionally supplemented with a suitable pigment to colour the cable for identification purposes.

15 According to the present invention, with the term natural magnesium hydroxide it is meant magnesium hydroxide obtained by grinding minerals based on magnesium hydroxide, such as brucite and the like. Brucite is found in its pure form or, more often, in
20 combination with other minerals such as calcite, aragonite, talc or magnesite, often in stratified form between silicate deposits, for instance in serpentine asbestos, in chlorite or in schists.

For the purposes of the present invention, brucite
25 can be ground according to known techniques, under wet or dry conditions, preferably in the presence of grinding coadjuvants, for example polyglycols or the like. The specific surface of the ground product is generally between 5 and 20 m²/g, preferably between 6 and 15 m²/g.
30 The magnesium hydroxide thus obtained can then be classified, for example by sieving, to obtain an average particle diameter generally of between 1 and 15 µm, preferably between 1.5 and 5 µm, and a particle size distribution such that not more than 10% of the total
35 number of particles have a diameter lower than 1.5 µm,

and not more than 10% of the total number of particles have a diameter greater than 20 μm .

Natural magnesium hydroxide generally contains various impurities derived from salts, oxides and/or hydroxides of other metals such as Fe, Mn, Ca, Si, V, etc. Amount and nature of the impurities can vary depending on the source of the starting mineral. The degree of purity is generally between 80 and 98% by weight. As regards water-soluble ionic-type impurities, their content can be determined indirectly by measuring electrical conductivity of an aqueous extract obtained by placing magnesium hydroxide in contact with a suitable amount of water for a predetermined period of time at a predetermined temperature. A more detailed description of this measurement, based on ISO method 787, is given hereinbelow. According to this method, electrical conductivity of the aqueous extract obtained from natural magnesium hydroxide is generally between 100 and 500 $\mu\text{S/cm}$, preferably between 120 and 350 $\mu\text{S/cm}$.

The natural magnesium hydroxide according to the present invention can be used as such or in the form of particles whose surface has been treated with saturated or unsaturated fatty acids containing from 8 to 24 carbon atoms, or metal salts thereof, such as, for example: oleic acid, palmitic acid, stearic acid, isostearic acid, lauric acid; magnesium or zinc stearate or oleate; and the like. To increase compatibility with the polymer matrix, natural magnesium hydroxide can also be surface-treated with suitable coupling agents, for example organic silanes or titanates such as vinyltriethoxysilane, vinyltriacetylsilane, tetraisopropyltitanate, tetra-n-butylyltitanate, and the like.

Using Scanning Electron Microscopy (SEM), it has been observed that natural magnesium hydroxide has a highly irregular granular morphology in terms both of its

geometrical shape and of its surface appearance. In contrast, the magnesium hydroxide obtained by precipitation consists of flattened hexagonal crystallites that are substantially uniform both in size and morphology.

5 As regards the copolymers (b), they are generally characterized by a narrow molecular weight distribution, with an index of molecular weight distribution (MWD), defined as the ratio between the weight-average molecular weight M_w and the number-average molecular weight M_n , of
10 less than 5, preferably between 1.5 and 3.5. The molecular weight distribution index can be determined, according to conventional methods, by Gel Permeation Chromatography (GPC).

With alpha-olefin it is meant an olefin of formula
15 $\text{CH}_2=\text{CH}-\text{R}$, wherein R is a linear or branched alkyl having from 1 to 10 carbon atoms. The alpha-olefin can be selected, for example, from propylene, 1-butene, 1-pentene, 4-methyl-1-pentene, 1-hexene, 1-octene, 1-dodecene and the like. Propylene, 1-hexene and 1-octene
20 are particularly preferred.

When the alpha-olefin is propylene, the copolymers (b) are also characterized by high regioregularity in the sequence of monomer units. In particular, these copolymers have a number of $-\text{CH}_2-$ groups in $-(\text{CH}_2)_n-$
25 sequences, where n is an even integer, relative to the total number of $-\text{CH}_2-$ groups, generally lower than 5% by mole, preferably lower than 1% by mole. This quantity can be determined according to known techniques by means of ^{13}C -NMR analysis.

30 When a diene comonomer is present, it generally has from 4 to 20 carbon atoms, and is preferably selected from: linear, conjugated or non-conjugated diolefins, for example 1,3-butadiene, 1,4-hexadiene or 1,6-octadiene; monocyclic or polycyclic dienes, for example 1,4-
35 cyclohexadiene, 5-ethylidene-2-norbornene, 5-methylene-2-

norbornene, and the like.

In general, for the purposes of the present invention, the desired mechanical and thermocompression resistance characteristics of the flame-retardant coating
5 may be obtained using polymer mixtures comprising from 5 to 60% by weight, preferably from 10 to 40% by weight, of a crystalline propylene homopolymer or copolymer (a), and from 40 to 95% by weight, preferably from 60 and 90% by weight, of a copolymer (b), the percentages being
10 referred to the total weight of the polymeric components (a) and (b).

Within the class of copolymers (b) as defined above, two main groups of products can be distinguished.

The first group (b1) consists of copolymers of
15 ethylene with at least one C₃-C₁₂ alpha-olefin, and optionally a diene, these copolymers having elastomeric properties and preferably characterized by:

- melting enthalpy lower than 35 J/g, preferably lower than 30 J/g;

- 20 - intrinsic viscosity $[\eta]$ generally greater than 1.0 dl/g, preferably greater than 2.0 dl/g (determined in tetralin at 135°C);

- Mooney viscosity ML(1+4) at 125°C (measured according to Standard ASTM D1646) generally greater than
25 10, preferably of from 20 to 90;

- solubility in pentane at 20°C generally greater than 80% by weight;

- tension set at 200% (measured at 20°C for 1 minute according to ASTM standard D 412) lower than 30%.

30 Tension set provides a measure of the elastic recovery properties of the non-crosslinked material. This is determined by subjecting a sample of the tested material to a tensile force such as to obtain an elongation of 200% for a predetermined period. After

removing the stress, the permanent deformation of the sample, which is expressed as a percentage relative to its initial dimensions, is measured: the smaller this value, the better the elastic properties of the material.

5 The copolymers belonging to group (b1) generally have the following composition: 35-90% by mole of ethylene; 10-65% by mole of alpha-olefin, preferably propylene; 0-10% by mole of a diene, preferably 1,4-hexadiene or 5-ethylidene-2-norbornene. When the alpha-
10 olefin is propylene, the monomer composition is preferably as follows: 55-80% by weight, preferably 65-75% by weight, of ethylene; 20-45% by weight, preferably 25-35% by weight, of propylene; 0-10% by weight, preferably 0-5% by weight, of a diene (preferably 5-
15 ethylene-2-norbornene). When the alpha-olefin is propylene, the propylene units are in the form of triads generally in amounts of between 4 and 50% by mole with respect to the total amount of propylene, and at least 70% of these triads have isotactic structure, as shown by
20 ¹³C-NMR analysis.

The second group (b2) consists of copolymers of ethylene with at least one C₄-C₁₂ alpha-olefin, preferably 1-octene, and optionally a diene, preferably characterized by:

- 25 - a density of between 0.86 and 0.90 g/cm³;
 - a melting enthalpy of between 30 and 60 J/g;
 - Melt Flow Index (MFI), measured according to ASTM standard D 1238/L, of between 0.1 and 30 g/10 min, preferably between 0.5 and 5 g/10 min.

30 The copolymers belonging to group (b2) generally have the following composition: 75-97% by mole, preferably 90-95% by mole, of ethylene; 3-25% by mole, preferably 5-10% by mole, of alpha-olefin; 0-5% by mole, preferably 0-2% by mole, of a diene.

35 The copolymers (b) can be obtained by

copolymerization of ethylene with an alpha-olefin, and optionally with a diene, in the presence of a "single-site" catalyst, for example a metallocene catalyst, as described, e.g., in patent applications WO 93/19107 and
5 EP-A-632,065 (for the copolymers of group (b1)) or in patents US-5,246,783 and US-5,272,236 (for the copolymers of group (b2)). The metallocenes used to polymerize the olefins are coordination complexes of a transition metal, usually of Group IV, in particular titanium, zirconium or
10 hafnium, with two optionally substituted cyclopentadienyl ligands, used in combination with a co-catalyst, for example an alumoxane, preferably methylalumoxane, or a boron compound (see for example J.M.S.-Rev. Macromol. Chem. Phys., C34(3), 439-514 (1994); J. Organometallic
15 Chemistry, 479 (1994), 1-29, or patents US-5,272,236, US-5,414,040 and US-5,229,478, or the above-mentioned patent applications WO 93/19107 and EP-A-632065, and patents US-5,246,783 and US-5,272,236). Catalysts which are suitable for obtaining the copolymers (b) according to the present
20 invention are also the so-called "Constrained Geometry Catalysts" described, for example, in patents EP-416,815 and EP-418,044.

The crystalline propylene homopolymers or copolymers (a) generally have a melting enthalpy greater than 75
25 J/g, preferably greater than 85 J/g. They may be selected in particular from:

- (1) isotactic propylene homopolymers with an isotacticity index greater than 80, preferably greater than 90, even more preferably greater than 95;
- 30 (2) propylene homopolymers obtainable by using metallocene catalysts, having a pentad mmmm content greater than 90% (determined by ¹³C-NMR analysis);
- (3) crystalline copolymers of propylene with ethylene and/or an alpha-olefin having from 4 to 10

carbon atoms, with an overall content of ethylene and/or alpha-olefin lower than 10% by mole;

(4) heterophasic propylene copolymers obtainable by polymerization in sequence of propylene and of mixtures
5 of propylene with ethylene and/or an alpha-olefin having from 4 to 10 carbon atoms, containing at least 70% by weight of polypropylene homopolymer or of crystalline propylene/ethylene copolymer, with an isotacticity index greater than 80, the remainder consisting of an
10 elastomeric ethylene/propylene copolymer with a propylene content of between 30 and 70% by weight;

(5) crystalline propylene homopolymers or copolymers having syndiotactic structure obtainable by using metallocene catalysts.

15 The amount of magnesium hydroxide which is suitable for imparting the desired flame-retardant properties can vary within a wide range, generally between 10 and 90% by weight, preferably between 30 and 80% by weight, with respect to the total weight of the composition.

20 Other fillers with flame-retardant properties can optionally be added to the natural magnesium hydroxide, for example aluminium hydroxide or alumina trihydrate ($\text{Al}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$). One or more inorganic oxides or salts such as CoO , TiO_2 , Sb_2O_3 , ZnO , Fe_2O_3 , CaCO_3 or mixtures thereof
25 can advantageously also be added in small amounts, generally less than 25% by weight.

With the aim of improving compatibility between magnesium hydroxide and polymer matrix, a coupling agent capable of increasing the interaction between the
30 hydroxyl groups of magnesium hydroxide and the polyolefin chains may be added to the mixture. This coupling agent can be selected from those known in the art, for example: saturated silane compounds or silane compounds containing at least one ethylenic unsaturation; epoxides containing

an ethylenic unsaturation; monocarboxylic acids or, preferably, dicarboxylic acids having at least one ethylenic unsaturation, or derivatives thereof, in particular anhydrides or esters.

5 Examples of silane compounds which are suitable for this purpose are: γ -methacryloxypropyl-trimethoxysilane, methyltriethoxysilane, methyltris (2-methoxyethoxy)-silane, dimethyldiethoxysilane, vinyltris (2-methoxyethoxy)silane, vinyltrimethoxysilane, vinyl-
10 triethoxysilane, octyltriethoxysilane, isobutyltriethoxysilane, isobutyltrimethoxysilane and mixtures thereof.

 Examples of epoxides containing an ethylenic unsaturation are: glycidyl acrylate, glycidyl
15 methacrylate, monoglycidyl ester of itaconic acid, glycidyl ester of maleic acid, vinyl glycidyl ether, allyl glycidyl ether, or mixtures thereof.

 Monocarboxylic or dicarboxylic acids, having at least one ethylenic unsaturation, or derivatives thereof,
20 which can be used as coupling agents are, for example: maleic acid, maleic anhydride, fumaric acid, citraconic acid, itaconic acid, acrylic acid, methacrylic acid and the like, and anhydrides or esters derived therefrom, or mixtures thereof. Maleic anhydride is particularly
25 preferred.

 The coupling agents can be used as such or pre-grafted onto a polyolefin, for example polyethylene or copolymers of ethylene with an alpha-olefin, by means of a radicalic reaction (see for example patent EP-530,940).
30 The amount of grafted coupling agent is generally between 0.05 and 5 parts by weight, preferably between 0.1 and 2 parts by weight, with respect to 100 parts by weight of polyolefin. Polyolefins grafted with maleic anhydride are available as commercial products known, for example,

under the trademarks Fusabond® (Du Pont), Orevac® (Elf Atochem), Exxelor® (Exxon Chemical), Yparex® (DSM), etc.

Alternatively, the coupling agents of carboxylic or epoxide type mentioned above (for example maleic anhydride) or the silanes with ethylenic unsaturation (for example vinyltrimethoxysilane) may be added to the mixture in combination with a radical initiator so as to graft the compatibilizing agent directly onto the polymer matrix. An organic peroxide such as tert-butyl perbenzoate, dicumyl peroxide, benzoyl peroxide, di-tert-butyl peroxide and the like can, for example, be used as initiator. This method is described, for example, in patent US-4,317,765 or in Japanese patent application JP-62-58774.

The amount of coupling agent that can be added to the mixture can vary mainly depending on the type of coupling agent used and on the amount of magnesium hydroxide added, and is generally between 0.01 and 5%, preferably between 0.05 and 2%, by weight relative to the total weight of the base polymer mixture.

Other conventional components such as antioxidants, processing coadjuvants, lubricants, pigments, other fillers and the like can be added to the compositions of the present invention.

Conventional antioxidants which are suitable for this purpose are, for example: polymerized trimethyldihydroquinoline, 4,4'-thiobis(3-methyl-6-tert-butyl)phenol; pentaerythritol tetrakis[3-(3,5-di-tert-butyl-4-hydroxyphenyl)propionate], 2,2'-thio-diethylene-bis-[3-(3,5-di-tert-butyl-4-hydroxy-phenyl)propionate] and the like, or mixtures thereof.

Other fillers which may be used in the present invention include, for example, glass particles, glass fibres, calcined kaolin, talc and the like, or mixtures thereof. Processing co-adjuvants usually added to the

polymer base are, for example, calcium stearate, zinc stearate, stearic acid, paraffin wax, silicone rubbers and the like, or mixtures thereof.

The flame-retardant compositions according to the present invention can be prepared by mixing the polymer components and the additives according to methods known in the art. The mixing can be carried out, for example, using an internal mixer of the type with tangential rotors (Banbury) or with interpenetrating rotors, or alternatively in continuous mixers such as those of the type Ko-Kneader (Buss), or of the type co-rotating or counter-rotating twin-screw. The flame-retardant compositions according to the present invention are preferably used in non-crosslinked form, to obtain a coating with thermoplastic properties and thus recyclable.

It is also possible to carry out a partial crosslinking of the polymer matrix according to methods known in the art, in particular by dynamic crosslinking, i.e. by adding a suitable radical initiator to the mixture during processing, for example an organic peroxide, optionally in the presence of a crosslinking co-agent such as, for example, 1,2-polybutadiene, triallylcyanurate or triallyl-isocyanurate. Dynamic crosslinking techniques are described, for example, in patents US-Re.31,518, US-4,130,535, US-4,348,459, US-4,948,840, US-4,985,502, EP-618,259. The mixture is processed at the vulcanization temperature specific to the radical initiator used, using a conventional mixer chosen, for example, from those mentioned above. At the end of the dynamic crosslinking, a partially crosslinked material is obtained in which thermoplastic properties and thus processability are retained, since a crosslinked phase is formed consisting of ethylene/alpha-olefin or ethylene/alpha-olefin/diene copolymer, which is dispersed

in a thermoplastic phase consisting of non-crosslinked polypropylene. A person skilled in the art will be able to dose the radical initiator and the optional crosslinking co-agent suitably depending both on the
5 specific conditions under which the dynamic crosslinking is carried out, and on the properties desired for the final product, in particular as regards the crosslinking degree.

As an alternative to organic peroxides, dynamic
10 crosslinking can be carried out in the presence of non-peroxidic radical initiators, such as alkyl derivatives of 1,2-diphenylethane (see for example patent EP-542,253).

The polymer mixtures, optionally partially
15 crosslinked as described above, can then be used to coat the conductor directly, or to make an outer sheath on the conductor previously coated with an insulating layer. This step can be carried out, for example, by extrusion. When two layers are present, the extrusion can be carried
20 out in two separate stages, extruding the inner layer onto the conductor in a first run and the outer layer onto this inner layer in a second run. Advantageously, the coating process can be carried out in a single run, for example by means of a "tandem" method, in which two
25 separate extruders arranged in series are used, or alternatively by co-extrusion using a single extrusion head.

The following working examples are given to illustrate the present invention more clearly.

30 The following types of magnesium hydroxide were used as flame-retardant fillers:

TABLE 1

Name	Type	Conductivity of the aqueous extract ($\mu\text{S}/\text{cm}$)	Specific surface (m^2/g)	Particle size curve (μm)		
				10%	50% (average)	90%
Kisuma® 5A	synthetic	74	7.1	0.8	1.6	3.1
Hydrofy® G-2.5	natural	135	8.2	0.5	2.6	9.8
Hydrofy® GS-1.5	natural	190	10.4	0.7	2.1	6.4

The products Kisuma® 5A (from the company Kyowa Chemical Ind.) and Hydrofy® GS-1.5 (from the company SIMA) are surface-treated with stearic acid, while the product Hydrofy® G-2.5 (SIMA) is untreated.

The specific surface was measured by the BET method. The samples were previously subjected to a treatment under vacuum at a temperature of 130°C for 24 hours to eliminate any adsorbed extraneous products, and then nitrogen was adsorbed (adsorption isotherm at -196°C , assuming an area of 16.2 \AA^2 for the nitrogen molecule; apparatus used: Sorptomatic 1900 - Carlo Erba).

The particle size distribution curve was obtained from suspensions of the samples of magnesium hydroxide in ethanol, using a helium-neon laser diffraction granulometer (Cilas-Alcatel Model HR850). The measurements were taken after ultrasonic treatment with stirring for 120 sec to ensure complete deflocculation of the test samples. The average particle diameter was obtained from the cumulative particle size distribution curves.

The content of water-soluble impurities was evaluated indirectly by measuring the conductivity of the

aqueous extract, namely of an aqueous solution left in contact with the magnesium hydroxide for a predetermined period of time. In particular, the test was carried out in the following way.

5 20.0 \pm 0.1 g of magnesium hydroxide are suspended in 40 ml of ethanol with stirring. 160 ml of deionized water (conductivity of less than 1.5 μ S/cm) are then added and the suspension is stirred using a magnetic stirrer for one hour. The suspension is subsequently filtered to
10 separate out the magnesium hydroxide. A measurement of conductivity (A) is carried out on the resulting solution and is compared with the conductivity (B) of a solution consisting of 40 ml of ethanol in 160 ml of deionized water. The conductivity of the aqueous extract (C) is
15 then calculated as:

$$C = A - B \quad (\mu\text{S/cm}).$$

As regards the polymeric products, the reported properties were obtained as follows:

- second melting enthalpy (ΔH_{2m}) and second melting
20 point (T_{2m}): obtained by differential scanning calorimetry (DSC) with a scanning speed of 10°C/min;

- Melt Flow Index (MFI): measured according to ASTM standard D 1238/L (at 230°C and 21.6 N for polypropylene, and at 190°C and 21.6 N for ethylene/1-octene
25 copolymers);

- composition distribution index (CDI): determined by temperature rising elution fractionation methods.

Preparation of the flame-retardant compositions.

The mixtures of Examples 1-12 and 23-24 were
30 prepared in a closed Banbury mixer (volume of the mixing chamber: 1200 cm³) with a volume filling of 95%. The mixing was carried out at a temperature of 200°C for a total time of 10 min (rotor speed: 44 revolutions/min). The Mooney viscosity of the resulting mixture was

determined at 130°C according to ASTM standard D-1646.

The mixtures of Examples 13-22 were prepared in a Brabender mixer (volume of the mixing chamber: 80 cm³) filled to a volume filling of 95%. The mixing was carried out at a temperature of 170°C for a total time of 10 min (rotor speed: 40 revolutions/min). At the end the final torque was measured under the above-mentioned mixing conditions.

Mechanical properties.

10 The flame-retardant compositions were subjected to mechanical tensile strength tests according to CEI standard 20-34, § 5.1 on specimens taken from 1 mm-thick plates obtained by compression moulding at 190-195°C and 200 bar after preheating for 5 min at the same temperature.

The same mechanical strength tests were carried out on cable specimens obtained by extruding the mixtures onto a single wire of red copper (section 1.5 mm²; diameter: 1.4 mm) in an extruder with a cylinder having a 45 mm diameter and with a length equal to 25 diameters (final thickness of the insulating layer: 0.7 mm).

Measurement of oxygen index (LOI).

The oxygen index was measured, according to ASTM standard D 2863, on plates obtained as described for the mechanical tests, but with a thickness of 3 mm.

Measurement of flame-resistance.

The cable specimens prepared as described above were subjected to the flame-resistance test according to CEI standard 332-1, which consists in subjecting a 60 cm long sample, placed vertically, to the direct action of a Bunsen flame applied for 1 min at an inclination of 45° relative to the sample.

Measurement of insulation constant (Ki)

The insulation constant (Ki) at 20°C was measured according to CEI standard 20-11 B6, on a cable specimen

obtained as described above.

Examples 1-4 (comparative)

For comparative purposes, a number of flame-retardant compositions were prepared according to the prior art, in which the polymer base consisted of a mixture of two ethylene/vinyl acetate copolymers with linear low density polyethylene (LLDPE), using magnesium hydroxide of natural origin or synthetic magnesium hydroxide. The compositions (in phr, i.e. parts by weight per 100 parts of polymer matrix) and the results of the mechanical strength and flame resistance tests as described above are given in Table 2.

5 The results given in Table 2 clearly demonstrate that natural magnesium hydroxide used in combination with conventional polymer mixtures does not give satisfactory results in terms both of mechanical properties and of flame resistance, whereas good results are obtained with synthetic magnesium hydroxide (used in the same amount in
10 the mixture).

In particular, it is believed that the poor results obtained with natural magnesium hydroxide, in terms of fire resistance, are due to the poor dispersion of this magnesium hydroxide in the polymer mixture.

15 EXAMPLES 5-8

A number of flame-retardant compositions were prepared, in which the polymer base consisted of a mixture of polypropylene (Moplen® EP 1X 35 HF - Montell) and an ethylene/1-octene copolymer (Engage® 8003 - Du
20 Pont-Dow Elastomers) obtained by metallocene catalysis, with uniform distribution of the 1-octene comonomer between the copolymer molecules (composition distribution index (CDI) >70%). Natural magnesium hydroxide or synthetic magnesium hydroxide was used as flame-retardant
25 filler. The compositions, in phr, and the results of the mechanical strength and flame re-sistance tests as described above are given in Table 3.

5 As a comment to the results given in Tables 2-6, it can be noticed that, according to the experiments carried out by the Applicant and in confirmation of the teachings obtainable from the prior art, the use of natural magnesium hydroxide as flame-retardant filler for

10 polyolefin-based compositions of conventional type, obtained by (co)polymerization of the corresponding olefins in the presence of conventional Ziegler-Natta catalysts, i.e. not "single-site" catalysts, leads to a remarkable reduction in flexibility and mechanical

15 strength properties of the material, as demonstrated by low values of stress at break and elongation at break. Moreover, the flame-retardant effect which can be obtained is, in any event, modest, as demonstrated by the measurements of oxygen index and of direct combustion by

20 flame.

Conversely, according to the present invention, the Applicant has found that compositions comprising natural magnesium hydroxide and a polymer mixture of

polypropylene and an ethylene/alpha-olefin or ethylene/alpha-olefin/diene copolymer, with uniform distribution of the alpha-olefin among the copolymer molecules, are characterized by very good mechanical and elastic properties, that are comparable to those obtainable by using synthetically produced (by precipitation) magnesium hydroxide as flame-retardant filler. Improved processability of the polymer mixture has also been observed, as demonstrated by low values of torque measured on systems filled with magnesium hydroxide after the mixing process, these values being essentially unchanged with respect to mixtures which do not contain flame-retardant fillers. Moreover, these mixtures, and the cables made therefrom, have excellent flame-retardant properties, which are essentially comparable to those of mixtures and cables using synthetic magnesium hydroxide; one interpretation of this result is that, in particular by virtue of the choice of ethylene/alpha-olefin or ethylene/alpha-olefin/diene copolymer, the mixture according to the present invention allows better and more homogeneous dispersion of the magnesium hydroxide in the polymer bulk.

EXAMPLES 23-24

Cable specimens were prepared as described above for mechanical tests, using the compositions given in Table 7. These cables were subjected to the thermocompression test according to CEI standard 20-34/3-1 at increasing temperatures. The results are reported in Table 7.

5

As can be noticed, the composition containing polypropylene passes the thermocompression test even at 100-110°C, whereas the composition devoid of polypropylene fails the test even at 100°C and there is complete piercing at 110°C.

10

CLAIMS

1. Cable with self-extinguishing properties, comprising a conductor and a flame-retardant coating, 5 characterized in that the said flame-retardant coating comprises:

(a) a crystalline propylene homopolymer or copolymer;

(b) a copolymer of ethylene with at least one alpha-olefin, and optionally with a diene, said copolymer (b) 10 being characterized by a composition distribution index greater than 45%, said index being defined as the weight percentage of copolymer molecules having an alpha-olefin content within 50% of the average total molar content of 15 alpha-olefin;

(c) natural magnesium hydroxide in an amount such as to impart flame-retardant properties.

2. Cable according to claim 1, wherein an electrically insulating inner layer is present and 20 wherein the flame-retardant coating is placed externally to said inner layer.

3. Cable according to claim 1, wherein the flame-retardant coating is placed on the conductor and is electrically insulating.

25 4. Cable according to any one of the preceding claims, wherein the magnesium hydroxide (c) has a specific surface of between 5 and 20 m²/g.

5. Cable according to claim 4, wherein the magnesium hydroxide (c) has a specific surface of between 6 and 15 30 m²/g.

6. Cable according to any one of the preceding claims, wherein the magnesium hydroxide (c) has an average particle diameter of between 1 and 15 μm, and a particle size distribution such that not more than 10% of

the total number of particles have a diameter lower than 1.5 μm and not more than 10% of the total number of particles have a diameter greater than 20 μm .

7. Cable according to any one of the preceding
5 claims, wherein the electrical conductivity of the aqueous extract obtained from the magnesium hydroxide (c) is between 100 and 500 $\mu\text{S}/\text{cm}$.

8. Cable according to claim 7, wherein the
10 electrical conductivity of the aqueous extract obtained from the magnesium hydroxide (c) is between 120 and 350 $\mu\text{S}/\text{cm}$.

9. Cable according to any one of the preceding claims, wherein the magnesium hydroxide (c) is used as such.

15 10. Cable according to any one of claims from 1 to 8, wherein the magnesium hydroxide (c) is used in the form of particles surface-treated with saturated or unsaturated fatty acids containing from 8 to 24 carbon atoms, or metal salts thereof.

20 11. Cable according to any one of claims from 1 to 8, wherein the magnesium hydroxide is surface-treated with a coupling agent.

12. Cable according to claim 11, wherein the coupling agent is an organosilane or organotitanate.

25 13. Cable according to any one of the preceding claims, wherein in the copolymer (b) the alpha-olefin has the formula $\text{CH}_2=\text{CH}-\text{R}$, where R is a linear or branched alkyl having from 1 to 10 carbon atoms.

30 14. Cable according to any one of the preceding claims, wherein the copolymer (b) has a molecular weight distribution index (MWD) lower than 5.

15. Cable according to claim 14, wherein the copolymer (b) has a molecular weight distribution index (MWD) of from 1.5 to 3.5.

16.Cable according to any one of the preceding claims, wherein the copolymer (b) is obtainable by copolymerization of ethylene with at least one C₃-C₁₂ alpha-olefin, and optionally with a diene, in the presence of a single-site catalyst.

17.Cable according to claim 16, wherein the single-site catalyst is a metallocene catalyst.

18.Cable according to claim 16, wherein the single-site catalyst is a constrained geometry catalyst.

19.Cable according to any one of the preceding claims, wherein the copolymer (b) is a copolymer of ethylene with at least one C₃-C₁₂ alpha-olefin, and optionally a diene, this copolymer having elastomeric properties.

20.Cable according to claim 19, wherein the copolymer (b) has a melting enthalpy lower than 35 J/g.

21.Cable according to claim 19 or 20, wherein the copolymer (b) has an intrinsic viscosity $[\eta]$ in tetralin at 135°C greater than 1.0 dl/g.

22.Cable according to any one of claims from 19 to 21, wherein the copolymer (b) has a Mooney viscosity ML(1+4) at 125°C, measured according to ASTM D1646, greater than 10.

23.Cable according to any one of claims from 19 to 22, wherein the copolymer (b) has a solubility in pentane at 20°C greater than 80% by weight.

24.Cable according to any one of claims from 19 to 23, wherein the copolymer (b) has a value of tension set at 200%, measured at 20°C for 1 minute according to ASTM standard D 412, lower than 30%.

25.Cable according to any one of claims from 19 to 24, wherein the copolymer (b) has the following monomer composition: 35-90% by mole of ethylene; 10-65% by mole of alpha-olefin; 0-10% by mole of diene.

26. Cable according to any one of claims from 19 to 25, wherein the alpha-olefin is propylene.

27. Cable according to claim 26, wherein the copolymer (b) has the following monomer composition: 55-80% by weight of ethylene; 20-45% by weight of propylene; 0-10% by weight of diene.

28. Cable according to claim 27, wherein the copolymer (b) has the following monomer composition: 65-75% by weight of ethylene; 25-35% by weight of propylene; 0-5% by weight of diene.

29. Cable according to any one of claims from 1 to 18, wherein the copolymer (b) is a copolymer of ethylene with at least one C₄-C₁₂ alpha-olefin, and optionally a diene, this copolymer having a density of from 0.86 to 0.90 g/cm³.

30. Cable according to claim 29, wherein the copolymer (b) has a melting enthalpy of from 30 to 60 J/g.

31. Cable according to claim 29 or 30, wherein the copolymer (b) has a melt flow index (MFI), measured according to ASTM standard D 1238/L, of from 0.1 to 30 g/10 min.

32. Cable according to any one of claims from 29 to 31, wherein the copolymer (b) has the following composition: 75-97% by mole of ethylene; 3-25% by mole of alpha-olefin; 0-5% by mole of a diene.

33. Cable according to claim 32, wherein the copolymer (b) has the following composition: 90-95% by mole of ethylene; 5-10% by mole of alpha-olefin; 0-2% by mole of a diene.

34. Cable according to any one of claims 29 to 33, wherein the alpha-olefin is 1-octene.

35. Cable according to any one of the preceding claims, wherein the crystalline propylene homopolymer or

copolymer (a) has a melting enthalpy greater than 75 J/g.

36.Cable according to claim 35, wherein the crystalline propylene homopolymer or copolymer (a) has a melting enthalpy greater than 85 J/g.

5 37.Cable according to any one of the preceding claims, wherein the crystalline propylene homopolymer or copolymer (a) and the copolymer (b) are present in predetermined amounts, such as to confer to the flame-retardant coating predetermined properties of flexibility
10 and thermocompression resistance.

38.Cable according to claim 37, wherein the amount of propylene homopolymer or copolymer (a) is such that the flame-retardant coating has a thermocompression resistance value, measured at 100°C according to CEI
15 standard 20-34/3-1, greater than 50%.

39.Cable according to claim 37, wherein the copolymer (b) is present in an amount such that the flame-retardant coating has a value of elongation at break, measured according to CEI standard 20-34 § 5.1, of
20 at least 100%, and a value of modulus at 20%, measured according to CEI standard 20-34 § 5.1, lower than 12 MPa.

40.Cable according to claim 39, wherein the copolymer (b) is present in an amount such that the flame-retardant coating has a value of elongation at
25 break, measured according to CEI standard 20-34 § 5.1, of at least 150%, and a value of modulus at 20%, measured according to CEI standard 20-34 § 5.1, lower than 7 MPa.

41.Cable according to claim 37, wherein the flame-retardant coating comprises from 5 to 60% by weight of
30 the propylene homopolymer or copolymer (a) and from 40 to 95% by weight of the copolymer (b), these percentages being referred to the total weight of the polymeric components (a) and (b).

42.Cable according to claim 41, wherein the flame-

retardant coating comprises from 10 to 40% by weight of the propylene homopolymer or copolymer (a) and from 60 and 90% by weight of the copolymer (b), these percentages being referred to the total weight of the polymeric components (a) and (b).

43. Cable according to any one of the preceding claims, wherein the magnesium hydroxide (c) is present in an amount of between 10 and 90% by weight with respect to the total weight of the flame-retardant coating.

10 44. Cable according to claim 43, wherein the magnesium hydroxide (c) is present in an amount of between 30 and 80% by weight with respect to the total weight of the flame-retardant coating.

15 45. Cable according to any one of the preceding claims, wherein the flame-retardant coating further comprises a coupling agent capable of increasing compatibility between the magnesium hydroxide and the polymeric components.

20 46. Cable according to claim 45, wherein the coupling agent is selected from: saturated silane compounds or silane compounds containing at least one ethylenic unsaturation; epoxides containing an ethylenic unsaturation; monocarboxylic acids or, preferably, dicarboxylic acids having at least one ethylenic unsaturation, or derivatives thereof.

25 47. Cable according to claim 46, wherein the coupling agent is maleic anhydride.

30 48. Cable according to any one of claims 45 to 47, wherein the coupling agent has an ethylenic unsaturation and is added to the mixture in combination with a radical initiator, so as to graft the coupling agent directly onto the polymer matrix.

49. Cable according to claim 48, wherein the radical initiator is a peroxide.

50. Flame-retardant composition comprising:

(a) a crystalline propylene homopolymer or copolymer;

(b) a copolymer of ethylene with at least one alpha-olefin having from 3 to 12 carbon atoms, and optionally with a diene, said copolymer (b) being characterized by a composition distribution index greater than 45%, said index being defined as the weight percentage of copolymer molecules having an alpha-olefin content within 50% of the average total molar content of alpha-olefin;

(c) natural magnesium hydroxide in amounts such as to impart flame-retardant properties.

51. Flame-retardant composition according to claim 50, wherein the magnesium hydroxide is defined according to any one of claims from 4 to 12.

52. Flame-retardant composition according to claim 50 or 51, wherein the copolymer (b) is defined according to any one of claims from 13 to 34.

53. Flame-retardant composition according to any one of claims from 50 to 52, wherein the crystalline propylene homopolymer or copolymer (a) is defined according to claim 35 or 36.

54. Flame-retardant composition according to any one of claims from 50 to 53, wherein the crystalline propylene homopolymer or copolymer (a) and the ethylene copolymer (b) are present in predetermined amounts, defined according to any one of claims from 37 to 42.

55. Flame-retardant composition according to any one of claims from 50 to 54, wherein the magnesium hydroxide is present in an amount defined according to claim 43 or 44.

56. Flame-retardant composition according to any one of claims from 50 to 55, further comprising a coupling agent according to any one of claims 45 to 49.

57. Method for manufacturing a cable having improved mechanical properties and enhanced fire resistance, said method comprising the following steps: (1) preparing a polymer mixture with flame-retardant properties; (2) extruding said mixture on a conductor optionally pre-coated with an insulating layer, in order to obtain a flame-retardant coating, characterized in that step (1) comprises mixing a predetermined amount of natural magnesium hydroxide with:

10 (a) a crystalline propylene homopolymer or copolymer; and

(b) a copolymer of ethylene with at least one alpha-olefin, and optionally with a diene, which is capable of dispersing the natural magnesium hydroxide,

15 in predetermined amounts, so as to obtain superior processability for the mixture and superior mechanical properties for the flame-retardant coating.

58. Method according to claim 57, wherein the amount of natural magnesium hydroxide to be added is predetermined such as to obtain a cable which is capable of passing the fire resistance test according to CEI standard 332-1.

59. Method according to claim 57 or 58, wherein the amount of propylene homopolymer or copolymer (a) is such that the flame-retardant coating obtained after extrusion has a value of thermocompression resistance, measured at 100°C according to CEI standard 20-34/3-1, greater than 50%.

60. Method according to any one of claims from 57 to 59, wherein the amount of copolymer (b) is such that the flame-retardant coating obtained after extrusion has a value of elongation at break, measured according to CEI standard 20-34 § 5.1, of at least 100%, and a value of modulus at 20%, measured according to CEI standard 20-34

§ 5.1, lower than 12 MPa.

61. Method according to claim 60, wherein the amount of copolymer (b) is such that the flame-retardant coating obtained after extrusion has a value of elongation at break, measured according to CEI standard 20-34 § 5.1, of at least 150%, and a value of modulus at 20%, measured according to CEI standard 20-34 § 5.1, lower than 7 MPa.

62. Method for imparting improved mechanical properties and superior fire resistance to a cable, characterized in that said method comprises coating a conductor with a coating which comprises:

(a) a first predetermined amount of natural magnesium hydroxide;

(b) a second predetermined amount of a crystalline propylene homopolymer or copolymer; and

(c) a third predetermined amount of a copolymer of ethylene with at least one alpha-olefin, and optionally with a diene, which is capable of dispersing the natural magnesium hydroxide,

said first, second and third predetermined amounts being controlled so that said coating has an elongation at break better than a predetermined value and flame-retardant properties.
